Anaphylaxis and vaccination

Definition of anaphylaxis
There are many definitions of anaphylaxis in the literature and recently there has been considerable effort internationally to develop clear and consistent definitions and guidelines. The Australasian Society of Clinical Immunology and Allergy (ASCIA) define anaphylaxis as:

“Anaphylaxis is a rapidly evolving generalized multi-system allergic reaction characterized by one or more symptoms or signs of respiratory and/or cardiovascular involvement and involvement of other systems such as the skin and/or the gastrointestinal tract.”

Anaphylaxis is set apart from simple allergic reactions such as urticaria and asthma by the simultaneous involvement of several organ systems. The combination of cardiorespiratory symptoms with mucosal and/or skin changes is most specific.

Etiology
Anaphylaxis is triggered by the binding of allergen to specific immunoglobulin E (IgE). It implies previous exposure and sensitisation to the triggering substance or a cross reactive allergen. When an allergen binds to the IgE receptors on the surface of mast cells and basophils this results in cellular activation and degranulation. These cells release preformed mediators such as histamine and tryptase (an enzyme specific to mast cells) that elicit the signs and symptoms of anaphylaxis. This mechanism is also known as the Type 1 immediate hypersensitivity reaction.

“Anaphylactoid” reactions are clinically indistinguishable from anaphylaxis, but differ by their immune mechanism. As distinction between anaphylaxis and anaphylactoid reaction is impossible on the basis of clinical signs and symptoms alone, a clinical definition cannot differentiate between the two.

Treatment is the same.

Signs and symptoms of anaphylaxis
Symptoms/signs of respiratory/cardiovascular involvement are:

Respiratory
- Difficulty/noisy breathing
- Swelling of the tongue
- Swelling/tightness of the throat
- Difficulty talking and/or hoarse voice
- Wheezing or persistent cough

Cardiovascular
- Loss of consciousness
- Collapse
- Pale and floppy (in young children)
- Hypotension

Patients often report a sense of doom in the early phase of an anaphylactic episode.

The presence of mucosal/cutaneous signs is key to differentiating anaphylaxis from similar clinical syndromes with different etiology such as fainting or hypotonic hyporesponsive episode (HHE). Evidence of skin involvement is therefore required at level one of diagnosis.  

Anaphylaxis following immunisation
All vaccinations have the potential to produce an anaphylactic reaction, albeit very rarely. The incidence of anaphylaxis varies from less than one in a million to up to 3 per million. While this is a rare event, it is vital that it is recognised and managed well. The International Brighton Collaboration case definition and guidelines for anaphylaxis have provided the following diagnostic criteria.

Case definition of anaphylaxis following immunisation
Level 1 offers highly specific diagnosis while levels 2 and 3 are less specific but more sensitive so that all possible cases can be captured. Details about the severity should always be recorded.

For all levels of diagnostic certainty anaphylaxis is a clinical syndrome characterised by sudden onset AND
- rapid progression of signs and symptoms AND
- involving multiple (2) organ systems, as follows:

Level 3 − not specific
1 minor cardiovascular OR respiratory criterion AND
1 minor criterion from each of 2 different systems/categories.

Level 2 − not as specific however more sensitive
1 major cardiovascular AND
1 major respiratory criterion OR
1 major cardiovascular OR respiratory criterion AND
1 minor criterion involving 1 different system (other than cardiovascular or respiratory systems) OR
1 major dermatologic and 1 minor cardiovascular AND/OR minor respiratory criterion.

Level 1 − highly Specific for Anaphylaxis
1 major dermatological AND
1 major cardiovascular AND/OR
1 major respiratory criterion.

Early Warning

Emergency action!

Differentiating between anaphylaxis and a faint

### Clinical decision making around vaccines and potential anaphylaxis

- **Non-related symptoms e.g. allergy to cats**
  - **Vaccinate**
  - **History of sensitivities to vaccine/ingredient e.g. yeast**
  - **Clinical history, vaccinate observe**
- **History of anaphylaxis to vaccine or ingredient**
  - **Do not vaccinate without expert advice and advanced clinical support**
  - **Minor symptoms following vaccination**
  - **Clinical observation – alert clinicians**
- **Major symptoms**
  - **Initiate emergency response – refer to expert before further doses**
  - **Seek expert advice, can receive next dose**
  - **Resolves**
